

**Cab-over-engine vehicle with a non-tippable cab**

The present invention relates to a cab-over-engine (COE) freight vehicle which has a chassis and a driver's cab which is mounted untiltably on the chassis and situated  
5 above the vehicle's engine, which is supported by the chassis.

**State of the art**

Trucks may be divided into the two categories of "conventional trucks" and "COE  
10 trucks". Conventional trucks have their engine situated in front of the driver's cab and covered by a traditional bonnet which incorporates portions and panels/hatches which are easy to open (pivotalable aside) so that the engine is readily accessible for inspection and repair. At a given total vehicle length, however, this tandem positioning of the engine and the driver's cab results in occupation of part of the space in the  
15 longitudinal direction of the vehicle which could otherwise be used as load space. This limits the truck's load capacity, thereby impairing its transport economics.

To enable a larger proportion of a given total vehicle length to be used as effective load space, the trend has increasingly been towards building freight vehicles in the  
20 form of COE trucks, in which the driver's cab is situated over the engine. Part of the portion of the vehicle's total length which in conventional trucks is occupied by the engine and bonnet can therefore be utilised in COE trucks as load space, substantially increasing the vehicle's load capacity and improving its transport economics.

25 The fact that COE trucks have their engine situated under the floor of the driver's cab makes it necessary in practice for the cab to be tiltable forwards to enable the engine to be uncovered as necessary for servicing and repair purposes. A tiltable cab does entail, however, significant design problems due to the need for a special tilt mounting, mechanisms for locking the cab in the untilted driving position, and various  
30 devices which make the tilting movement possible and transmit motion between controls fitted in the cab (e.g. steering wheel, pedals, hand-operated controls etc.) and the front wheels, engine/gearbox, wheel brakes and other equipment mounted on the chassis. A further need is for flexible and stretchable wiring for transmitting electric

current and control signals between the driver's cab and the chassis and the equipment mounted on the chassis.

Object of the invention

5

The primary problem on which the invention is based is how to eliminate entirely the aforesaid design problems arising from the driver's cab being tiltable and at the same time provide the possibility of satisfactory access to the engine for servicing and repair, from either side of the vehicle, while still maintaining the COE truck's

10 "compactness" as regards the total cab/engine length.

An associated object of the invention is to provide a freight vehicle in which the wall elements which delineate the engine compartment laterally and are connected to and/or mounted on the chassis (e.g. panels, hatches etc), and other vehicle parts (e.g.

15 steps) alongside the engine, are easy to move out of the way or aside or to open so as to provide good access to the engine from both sides of the vehicle.

Description of the invention

20

In the kind of vehicle indicated in the introduction, the aforesaid problem is solved and the object achieved by the vehicle's exhibiting the constructional features indicated in the characterising part of claim 1.

Suka 47

25

Each side of the vehicle thus requires at least one panel which not only delineates the engine compartment laterally but may possibly also be provided with one or more steps and is attached by means of a special panel guide mechanism or guide which enables the panel to be pivoted outwards from the vehicle's centreline and rearwards in the longitudinal direction of the vehicle to a displaced position in which the panel no longer hinders the direct access to the engine required for carrying out engine

30 repair or inspection/servicing.

Suka 27

Preferred and advantageous embodiments of the freight vehicle according to the invention may also exhibit the further features indicated by the dependent patent claims.

5 In cases where the freight vehicle's chassis incorporates a frame structure in the form of a beam frame, a COE vehicle's engine will usually be situated at least partially between the parallel frame side members, particularly if the latter extend to the forward bumper at the front of the driver's cab.

10 To make access to the engine from the sides still easier in such cases, it is possible to have the frame side members ending in the region immediately to the rear of the rear of the engine. The engine is then not fitted between the frame side members but advantageously in a special arrangement which may consist of a beam structure or framework structure and which is designed to provide good access to the engine from  
15 both sides. A freight vehicle according to claim 2 may then be preferable.

If the panel delineating laterally the engine compartment is provided with external steps to help the driver climb up to/down from the cab, it is often desirable that these steps be concealed behind a special cover while the vehicle is in motion, to prevent  
20 the possibility of loose material (e.g. sand, gravel or small stones) accumulating or being caught on the steps, and also to help to reduce air resistance by providing the vehicle/driver's cab with more effective streamlining to reduce the risk of vortices that might generate resistance and cause dirt to adhere to the steps. The freight vehicle may therefore advantageously exhibit the constructional features indicated in claim 3.

25

*Sula37*  
To ensure that the aforesaid cover which in the closed position (e.g. while the vehicle is in motion) conceals the panel which carries the steps will automatically pivot away and uncover the steps when the cab door is opened, it is advantageous to have the cab door movement initiate and control the movement of the cover. A version of the  
30 freight vehicle according to claim 4 provides a practical solution in this respect.

Suba7 To avoid any risk of the driver's being hindered by the cover when he is climbing up to/down from the cab, it may be advantageous that the cab door and the associated cover be attached as indicated in claim 5.

- 5 A simple and robust version of the associated control arrangement may advantageously exhibit the features indicated in patent claims 6 and 7.

To provide optimum access to the vehicle engine for servicing and repair, it is preferable that the panel control arrangement be such that the panel can reliably move  
10 completely clear of the aperture which the cover coupled to the cab door uncovers as the door and cover open. An advantageous displaced position for the panel is then close to and alongside the vehicle's front wheel, with the panel "parked" parallel to the outside of the wheel.

- Suba57 15 A practical version of the panel control arrangement may then exhibit, for example, the constructional features indicated in claims 8 and 9.

Brief description of the drawings

- 20 The invention will now be illustrated and explained with reference to embodiments depicted in the attached drawings, which are as follows:

Fig. 1a depicts in schematic side view a COE truck with constructional features according to the present invention;

25

Fig. 1b depicts the left half of the driver's cab in Fig. 1a, viewed from above;

Fig. 2 depicts on a larger scale and in perspective a portion of a truck (of the kind depicted in Fig. 1) in the region of one of the cab's door apertures and the steps situated below;  
30

Fig. 3 depicts the same region of a truck as Fig. 2, but with the step panel displaced to a position alongside one of the truck's front wheels;

Fig. 4 depicts the step panel according to Fig. 3 viewed in a direction oblique to the wheel housing situated there;

5 Fig. 5 depicts on a still larger scale a control arrangement which absorbs relative motion and by which the truck's cab door is releasably coupled to a cover outside the step panel;

Fig. 6 depicts an enlarged detail of the control arrangement in Fig. 5;

10

Fig. 7 depicts on a larger scale the guide arm which is mounted on the wheel housing and which forms part of the step panel control arrangement according to Fig. 4.

15 Description of an embodiment

The invention is illustrated and explained in more detail below with reference to the driver's cab region of a COE (cab-over-engine) truck depicted as viewed from the side and from above in Figs. 1a and 1b respectively, and the portions and parts depicted in  
20 Figs. 2-7 which are primarily relevant to the invention.

The freight vehicle partially depicted in side view in Fig. 1 consists of a COE truck 2 with a chassis 4 and a driver's cab 6 mounted on the forward part of the chassis. The chassis incorporates in a conventional manner components not depicted here in more  
25 detail, such as power transmission elements and various items that are necessary for the vehicle's propulsion. The chassis 4 comprises a skeleton or frame structure which may in a conventional manner be made of steel beams or be composed of structural elements similar to box girders. The chassis and the more detailed construction of the chassis frame are nevertheless of no crucial significance for the present invention.

30 The truck relevant here is provided with a fixed cab, which means that the cab 6 is mounted untiltably relative to the chassis 4. The cab is also situated above the engine 7 (schematically depicted as a "block") which is supported by the chassis 4 of the vehicle 2 and which in this case may be regarded as fitted (suspended) in a special

suspension arrangement 8 composed of beams, rods or other loadbearing elements. This special suspension arrangement 8 supporting the engine 7 is then fastened to the forward portion of the frame side members of the chassis 4, the front ends 10 of which are situated in the region of the vehicle's front wheels 12.

5

On each side of the vehicle 2 there is a panel 14 which is mounted pivotably on the chassis 4 and which in its normal position of use (see Fig. 2) forms part of the sidewall of the engine compartment and thereby limits access to the engine from the outside. The panel 14 is provided on its outside with three steps 16, 18, 20 (see Figs. 2-4). The step panel 14 is mounted pivotably in the suspension arrangement 8 by means of a panel control arrangement which provides the panel with a movement displacing it from the normal position of use of the step panel (Fig. 2) by pivoting it outwards and rearwards in the longitudinal direction of the vehicle to an engine access position (see Figs. 3-4). In this displaced position the panel 14 is situated directly alongside a side cover 22 to the wheel housing 24 of the front wheel 12. In its normal retracted position of use (Fig. 2) when the vehicle is in motion the step panel 14 is concealed by a cover 26 which is hinge-mounted on the chassis 4 in the region directly below the cab door 28 situated there.

The cab door 28 and the cover 26 below the door are detachably coupled together by a control arrangement 30 which absorbs relative motion. It is via this control arrangement that the opening/closing of the cover 26 is controlled by the movement of the cab door 28. The control arrangement 30 is designed to allow a certain relative motion between the door and the cover. This is necessary to compensate for the individual springing motion of the cab 6 (and hence the cab door 28) relative to the cover 26 hinge-mounted on the chassis. The relative motion absorbing control arrangement 30 is also required to compensate for different hinge pin positioning on the door 28 and the cover 26. The hinge pin of the cover 26 is preferably situated slightly forward of the hinge pin of the door 28, as viewed in the forward direction of the vehicle and as depicted most clearly in Fig. 1b.

The construction, fastening and positioning of the control arrangement 30 relative to the door 28 and the cover 26 are depicted on a larger scale in Figs. 5 and 6, which will now be referred to.

5 The control arrangement 30 incorporates a slide rod 32, which is connected securely to the cover 26, and a sleeve 34 which is mounted for rotation and longitudinal movement relative to the slide rod and which is connected to the cab door 28 by jointed connecting devices 36,38,40,42,44. The slide rod 32 is fitted in a bracket 46 which is fastened to the upper part of the cover 26 and which incorporates a bottom  
10 plate 48 which is screwed firmly to the door 26 and which has end flanges 50,52 between which the slide rod 32 is fastened. The sleeve 34 has an external lever arm 36 which is connected via a ball joint 38, a fastening screw 40 and a fastening element 42 to a bracket 44 which is fastened to the lower part of the cab door 28. The fastening element 42 is riveted securely (by rivets 43) to the bracket 44.

15

A special type of panel control arrangement, the main parts of which are depicted in Fig. 4, is used for moving the step panel 14 from its normal retracted position of use (see Fig. 2) to its fully displaced position (see Figs. 3 and 4) which provides unobstructed access to the vehicle's engine via the aperture created jointly by the  
20 opening of the cab door 28 and the cover 26 (see Fig. 3).

The desired displacement movement of the step panel 14 is achieved by using for each panel a panel control arrangement incorporating a four-joint mechanism with two hinge arms 54,56 which have their outer ends 54',56' attached pivotingly to the inside  
25 of the panel 14. The hinge arms' inner ends 54'', 56'' are themselves attached pivotingly respectively to a framework 58 (connected to the chassis or the suspension arrangement 8) and a conical mounting 60. The mounting 60 is fastened on top of the wheel housing 24 of the front wheel 12.

30 To prevent the panel control arrangement becoming unsteady and unstable, the hinge arm 54 attached to the framework 58 takes the form of a gatelike unit incorporating two bent bars 62', 62'' which run parallel, are arranged substantially horizontally and are linked together by two vertically arranged parallel tiebars 64.

The step panel's other hinge arm 56 attached to the wheel housing consists, as indicated most clearly by Fig. 7, of a horizontally arranged bent rod 66, one end of which is attached to the conical mounting 60 by a setscrew 70 provided with a ball joint 68. The other end of the bent rod 66 is connected to the inside of the step panel 14 via a swivel 72 and a retaining yoke 74.
